**Summary:** in this tutorial, you will learn about MySQL view processing algorithms including

`MERGE` , `TEMPTABLE` , and `UNDEFINED` .

The `CREATE VIEW` and `ALTER VIEW` statements have an optional clause: `ALGORITHM` . The algorithm determines how MySQL process a view and can take one of three values `MERGE` , `TEMPTABLE` , and `UNDEFINE` .

Here is the `CREATE VIEW` statement with the `ALGORITHM` clause:

```
CREATE [OR REPLACE][ALGORITHM = {MERGE | TEMPTABLE | UNDEFINED}] VIEW
view_name[(column_list)]
AS
select-statement;
```

And this is the `ALTER VIEW` statement with the `ALGORITHM` clause:

```
CREATE [ALGORITHM = {MERGE | TEMPTABLE | UNDEFINED}] VIEW
view_name[(column_list)]
AS
select-statement;
```

# MERGE

When you query from a `MERGE` view, MySQL processes the following steps:

- First, merge the input query with the `SELECT` statement in the view definition into a single query.
- Then, execute the combined query to return the result set.

Note that the combination of input query and the `SELECT` statement of the view definition into a single query is referred to as *view resolution*.

See the following `customers` from the [sample database](#):

<b>customers</b>
* customerNumber
customerName
contactLastName
contactFirstName
phone
addressLine1
addressLine2
city
state
postalCode
country
salesRepEmployeeNumber
creditLimit

The following statement creates a view based on the `customers` table with the name `contactPersons` with the `MERGE` algorithm:

```
CREATE ALGORITHM=MERGE VIEW contactPersons(
    customerName,
    firstName,
    lastName,
    phone
) AS
SELECT
    customerName,
    contactFirstName,
    contactLastName,
```

```
    phone  
FROM customers;
```

Suppose that you issue the following statement:

```
SELECT * FROM contactPersons  
WHERE customerName LIKE '%Co%';
```

MySQL performs these steps:

- Convert view name `contactPersons` to table name `customers`.
- Convert asterisk (\*) to a list column names `customerName`, `firstName`, `lastName`, `phone`, which corresponds to `customerName`, `contactFirstName`, `contactLastName`, `phone`.
- Add the `WHERE` clause.

The resulting statement is:

```
SELECT  
    customerName,  
    contactFirstName,  
    contactLastName,  
    phone  
FROM  
    customers  
WHERE  
    customerName LIKE '%Co%';
```

## TEMPTABLE

When you issue a query to a `TEMPTABLE` view, MySQL performs these steps:

- First, [create a temporary table](#) to store the result of the `SELECT` in the view definition.
- Then, execute the input query against the temporary table.

Because MySQL has to create the temporary table to store the result set and moves the data from the base tables to the temporary table, the algorithm `TEMPTABLE` is less efficient than the

`MERGE` algorithm.

Note that `TEMPTABLE` views cannot be updatable.

## UNDEFINED

The `UNDEFINED` is the default algorithm when you create a view without specifying the `ALGORITHM` clause or you explicitly specify `ALGORITHM=UNDEFINED`.

In addition, when you create a view with `ALGORITHM = MERGE` and MySQL can only process the view with a temporary table, MySQL automatically sets the algorithm to `UNDEFINED` and generates a warning.

The `UNDEFINED` allows MySQL to choose either `MERGE` or `TEMPTABLE`. And MySQL prefers `MERGE` over `TEMPTABLE` if possible because `MERGE` is often more efficient than `TEMPTABLE`.

In this tutorial, you have learned about the MySQL view processing algorithms including `MERGE`, `TEMPTABLE`, and `UNDEFINED`.
